Problem 2

2025-09-24

NOTE: Data files must be in a 'Data' subdirectory relative to this R Markdown file

Problem 2:

[1] 1338

5

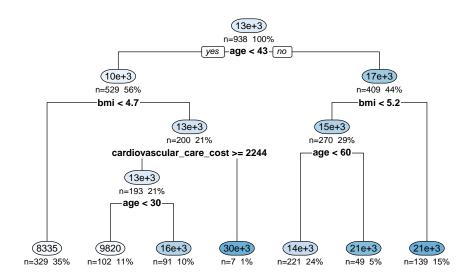

```
# Expected structure:
  - prob4.Rmd
   - Data/
      /- laptop_train.csv
      /- laptop_test.csv
setwd(dirname(rstudioapi::getSourceEditorContext()$path))
# Read CSV files using relative paths
df_orig <- read_csv("insurance_charges.csv")</pre>
## Rows: 1338 Columns: 5
## -- Column specification ----
## Delimiter: ","
## dbl (5): age, bmi, charges, f_bmi, cardiovascular_care_cost
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this message.

Question (c)

Residuals

The residuals are the differences between the actual charges in the test dataset and the predicted charges from the basetree model:

```
residual_i = y_i - \hat{y}_i
```

```
where
```

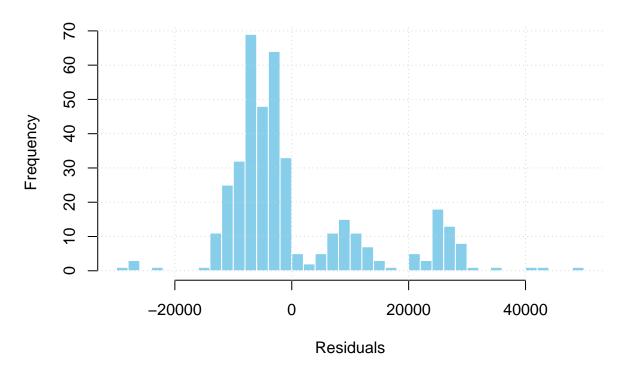

- y_i = actual charge for observation i (from the test dataset),
- \hat{y}_i = predicted charge for observation i (from the basetree).

```
# Calculate residuals on the test set
residuals <- df_test$charges - test_pred

# Summarize the residuals
residual_summary <- summary(residuals)
print(residual_summary)</pre>
```

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## -28105.4 -7162.4 -3882.3 292.7 5967.9 48770.3
```

Histogram of Residuals (Test Set)

Question (d)

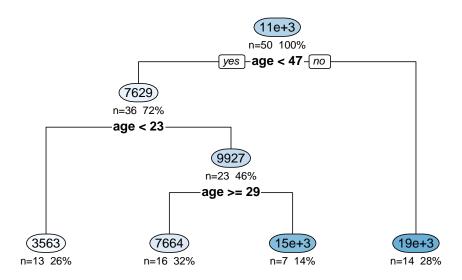

1. First we take a random sample with replacement of size 50 from the training set.

```
# Take random sample with replacement of size 50 from the training set
df_sample <- df_train[sample(nrow(df_train), 50, replace = TRUE), ]
# Check the dimensions of the sample
dim(df_sample)</pre>
```

[1] 50 5

2. Next, we fit a decision tree model to this sample, again with max depth 4.

Decision Tree on Sample (max depth = 4)

```
# Summary of the model
summary(tree_model_sample)
```

```

Histogram of R2 on Test Set (30 Sample Trees)

Results

Across the 30 bootstrapped trees (each trained on a random sample of 50 points with replacement, max depth = 4), the test-set R^2 values ranged from about -0.38 to +0.02, with most values negative. This means the bootstrapped trees generally performed worse than predicting the mean of the response. In contrast, the basetree (trained on the full training data with the same depth limit) achieved a small but positive R^2 of 0.0103, indicating that access to the full dataset led to slightly better generalization. A histogram of the 30 values would show them tightly clustered around negative performance, while the basetree stands just above zero.

The poor results arise mainly from two factors.

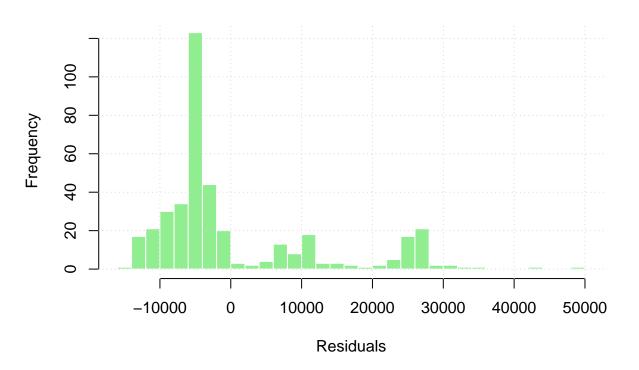

- 1. First, using only 50 observations in each bootstrap sample provides too little information, producing highly variable and weak models. Because sampling is done with replacement, some observations appear multiple times while others are skipped, reducing even further the variety of data the model sees.
- 2. Second, limiting tree depth to 4 constrains model complexity, so the trees cannot capture important structure in the data.

Question (f)

Now we are going to create WiseTree, an ensemble of 30 trees, each trained on a different bootstrap sample of size 50 (with replacement) from the training set, and each with max depth 4. In this ensemble, predictions are made by averaging the predictions of all 30 trees.

```
# Use the 30 pretrained trees from wise_tree_models
# Make predictions by averaging the predictions of all trees (WiseTree ensemble)
wise_tree_pred <- rowMeans(sapply(wise_tree_models, function(model)</pre>
                                    predict(model, newdata = df_test)))
# Calculate residuals for WiseTree
wise_tree_residuals <- df_test$charges - wise_tree_pred</pre>
# Summarize the residuals
wise_tree_residuals_summary <- summary(wise_tree_residuals)</pre>
print(wise_tree_residuals_summary)
       Min. 1st Qu.
                       Median
                                  Mean 3rd Qu.
                                                     Max.
## -14714.6 -6096.2 -4529.4
                                  545.1
                                          6140.9 48898.3
# Plot histogram of the residuals
hist(wise_tree_residuals, breaks = 40, main = "Histogram of WiseTree Residuals (Test Set)",
     xlab = "Residuals", col = "lightgreen", border = "white")
grid()
```

Histogram of WiseTree Residuals (Test Set)

Question (g)

Basetree: R-squared on test set = 0.0103

```
# Calculate R-squared for WiseTree on the test set
y_true <- df_test$charges
sse_wisetree <- sum((y_true - wise_tree_pred)^2)
sst <- sum((y_true - mean(y_true))^2)
R2_wisetree <- 1 - sse_wisetree/sst
cat(sprintf("WiseTree: R-squared on test set = %.4f\n", R2_wisetree))

## WiseTree: R-squared on test set = 0.0644

# Compare with basetree R2
cat(sprintf("Basetree: R-squared on test set = %.4f\n", R2_basetree))</pre>
```

WiseTree outperforms the basetree because it averages predictions from 30 bootstrapped trees, giving it more stability and better generalization. Bootstrapping samples the training set with replacement, so each tree sees a slightly different dataset, introducing diversity among the models. Averaging across these diverse but

shallow trees reduces variance, making WiseTree more reliable than a single tree trained on the full dataset.
